ReservedData2																															

ReservedData1 (44 bytes): A 44-byte array of reserved data.<1>

Dial ID (2 bytes): A 2-byte **Unicode character**. This field is used by the Callback Control Protocol to assert the validity of the **User Privilege** and **CallbackPhoneNumber** fields. The Callback Control Protocol compares the data contained in this field with Unicode character "d". If this field contains the aforementioned character, then the information inside the **User Privilege** and **CallbackPhoneNumber** fields is considered valid. If it contains a different value, then all information inside the **User Privilege** and **CallbackPhoneNumber** fields is considered invalid.

UserPrivilege (2 bytes): A 2-byte unsigned integer consisting of one or more of the following flags.

Value	Meaning
NoCallback 0x01	The answerer will not call back the user to establish a connection.
AdminSetCallback 0x02	When the user calls, the answer hangs up and calls a preset callback phone number stored in the **CallbackPhoneNumber** field.
CallerSetCallback 0x04	When the user calls, the answerer provides the option of specifying a callback phone number. The user can also choose to connect immediately without a callback. The **CallbackPhoneNumber** field MAY contain a default number that the caller can override.
DialinPrivilege 0x08	The user has permission to dial in to the Routing and Remote Access Services (RRAS) server.

CallbackPhoneNumber (48 bytes): This field is valid only if the **AdminSetCallback** or **CallerSetCallback** flag is set in the **User Privilege** field. This MUST specify a phone number that is configured for the user on which the answerer should call back.

ReservedData2 (2 bytes): Reserved data. <2>
